

Wide 4.5V-18V Input Voltage Range  
0.6V-7V Output Voltage Range  
8A Continuous Output Current  
Integrated 25m /12m Rdson of HS/LS Power MOSFETs  
Fixed 1ms Soft-start Time  
Selectable 400KHz, 800KHz and 1.2MHz Switching Frequencies  
Selectable PFM, USM and PWM Operation Modes  
Cycle-by-Cycle Current Limiting  
Output Over-Voltage Protection  
Over-Temperature Protection  
Available in a QFN2X3-12L Package

High End DTV  
Set-top Box, XDSL Modem, Personal Video Recorders  
Server, Cloud-Computing, Storage  
Telecom & Networking, Small-cell Base Stations, Point-of-Load ti  
IPCs, Factory Automation, Test Measurement

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Revision 1.0: Release to Market

Revision 1.4: Update char and typical application waveforms

Revision 1.5: Update AGND connection of application in page1 and page 12

Revision 1.6: Update DEVICE ORDER INFORMATION

Revision 1.7: Update ABS TJ max and add MSL information

ORDERABLE DEVICE	PACKAGING TYPE	STANDARD PACK QTY	PACKAGE MARKING	PINS	PACKAGE DESCRIPTION	MSL
SCT2280FPAR	Tape & Reel	5000	2280	12	QFN2X3-12L	1

Over operating free-air temperature unless otherwise noted<sup>(1)</sup>

FSEL	4	Switching frequency selection. Connecting to ground sets clock frequency to 400KHz. Floating sets clock frequency to 800KHz. Connecting to VCC sets clock frequency to 1.2MHz.
VOUT	5	VOUT is used to sense the output voltage of the buck regulator. Connect VOUT to the output capacitor of the regulator directly. Keep the VOUT sensing trace far away from the SW node. VIAs should also be avoided on the VOUT sensing trace. A trace larger than 25mil is required.
MODE	6	PFM, USM or FCCM mode selection. Connect the pin to VCC to force the device in Forced Continuous Current Modulation (FCCM) operation mode. Ground the pin to operate the device in Pulse Frequency Modulation (PFM) mode without Ultrasonic Mode (USM). Floating the pin to operate the device in PFM with USM.
SW	7	Connect SW to the inductor and bootstrap capacitor. SW is driven up to VIN through the high-side power MOSFET during on-time. The inductor current drives SW to negative voltage through low-side power MOSFET during off-time. Use wide and short PCB traces to make the connection. Keep the SW pattern area minimized.
BST	8	Bootstrap. Must connect a 0.1uF capacitor or greater between SW and BST to form a floating supply across the gate driver of high-side power MOSFET.
VCC	9	Internal VCC LDO output. The driver and control circuits are powered by VCC. Decouple with 1μF ceramic capacitor placed as close to VCC as possible.
AGND	10	Signal logic ground. AGND is the Kelvin connection to PGND.
FB	11	Feedback voltage Input. Connect FB to the tap of a resistor divider from output voltage to AGND to set up output voltage. The device regulates FB to the internal reference value of 0.6V typical.
EN	12	Enable logic input. EN is a digital input that controls the converter on v control

# SCT2280

(1) SCT provides  $R_{JA}$  and  $R_{JC}$  numbers only as reference to estimate junction temperatures of the devices.  $R_{JA}$  and  $R_{JC}$  are not a characteristic of package itself, but of many other system level characteristics such as the design and layout of the printed circuit board (PCB) on which the SCT2280 is mounted, thermal pad size, and external environmental factors. The PCB board is a heat sink that is soldered to the leads and thermal pad of the SCT2280. Changing the design or configuration of the PCB board changes the efficiency of the heat sink and therefore the actual  $R_{JA}$  and  $R_{JC}$ .

$V_{IN}=12V$ ,  $T_J=-40^{\circ}C\sim 125^{\circ}C$ , typical value is tested under  $25^{\circ}C$ .

# SCT2280

---

## Overview

The SCT2280 is a 4.5V-18V input, 8A continuous output synchronous buck converter with built-in 25m

efficiency in light load is much lower than heavy load.

**Enable and Under Voltage Lockout Threshold**

The SCT2280 is enabled when the VIN pin voltage rises above 4.25V and the EN pin voltage exceeds the enable threshold of 1.18V. The device is disabled when the VIN pin voltage falls below 3.98V or when the EN pin voltage is below 1.1V. An internal 1.5uA pull up current source to EN pin allows the device enable when EN pin floats.

EN pin is a high voltage pin that can be connected to VIN directly to start up the device.

For a higher system UVLO threshold, connect an external resistor divider (R1 and R2) shown in Figure 9 from VIN to EN. The UVLO rising and falling threshold can be calculated by Equation 1 and Equation 2 respectively.

Figure 9. System UVLO by enable divide

$$V_{rise} = \frac{V_{EN} \cdot R1}{R2} \tag{1}$$

$$V_{fall} = \frac{V_{EN} \cdot R1}{R2} \tag{2}$$

where

$V_{rise}$  is rising threshold of Vin UVLO

$V_{fall}$  is falling threshold of Vin UVLO

**Output Voltage**

The SCT2280 regulates the internal reference voltage at 0.6V with 1% tolerance over the operating temperature and voltage range. The output voltage is set by a resistor divider from the output node to the FB pin. It is recommended to use 1% tolerance or better resistors. Use Equation 3 to calculate resistance of resistor dividers. To improve efficiency at light loads, larger value resistors are recommended. However, if the values are too high, the regulator will be more susceptible to noise affecting output voltage accuracy.

$$V_{out} = \frac{V_{ref} \cdot (R_{FB\_TOP} + R_{FB\_BOT})}{R_{FB\_BOT}} \tag{3}$$

where

$R_{FB\_TOP}$  is the resistor connecting the output to the FB pin.

$R_{FB\_BOT}$  is the resistor connecting the FB pin to the ground.

**Internal Soft-Start**

The SCT2280 integrates an internal soft-start circuit that ramps the reference voltage from zero volts to 0.6V reference voltage in 1ms. If the EN pin is pulled below 1.1V, switching stops and the internal soft-start resets. The soft-start also resets during shutdown due to thermal overloading.

**Switching Frequency Selection**

The switching frequency of the SCT2280 is selectable to be one of three options: 400KHz, 800KHz and 1200KHz. The switching frequency selection is done by pulling the frequency select pin to ground or VCC.

## Over voltage Protection

The SCT2280 implements the Over-voltage Protection (OVP) circuitry to minimize output voltage overshoot during load transient, recovering from output fault condition or light load transient. The overvoltage comparator in OVP circuit compares the FB pin voltage to the internal reference voltage. When the feedback voltage rises higher than 122% of the feedback voltage, the OVP comparator output goes high and the circuit turns off the HS-FET driver. The LS-FET driver turns on until trigger negative current limit or FB below reference voltage. Then HS-FET turns on with normal ON-time and turn off, following with a LS-FET on until negative current limited triggered or FB lower than reference voltage. The device exits this regulation period when the feedback voltage falls below 117% of the reference voltage.

The SCT2280 offers output discharge under OVP and EN off condition. When OVP is triggered or EN is turn off, a discharge FET is turned on and VOUT pin is connected to a 78 discharge resistor.

## Thermal Shutdown

The SCT2280 protects the device from the damage during excessive heat and power dissipation conditions. Once the junction temperature exceeds 163C, the internal thermal sensor stops power MOSFETs switching. When the junction temperature falls below 133C, the device restarts with internal soft start phase.

## Typical Application

Figure 10. SCT2280 Design Example, 1V Output

### Design Parameters

Design Parameters	Example Value
Input Voltage	12V Normal 4.5V to 18V
Output Voltage	1V
Maximum Output Current	8 A
Switching Frequency	800 KHz
Output voltage ripple (peak to peak)	90mV

## Input Capacitor Selection

For good input voltage filtering, choose low-ESR ceramic capacitors. A ceramic capacitor 10 $\mu$ F is recommended for the decoupling capacitor and a 0.1 $\mu$ F ceramic bypass capacitor is recommended to be placed as close as possible to the VIN pin of the SCT2280.

Use Equation 4 to calculate the input voltage ripple:

\_\_\_\_\_

## Output Capacitor Selection

The selection of output capacitor will affect output voltage ripple in steady state and load transient performance.

The output ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance ESR of the output capacitors and the other is caused by the inductor current ripple charging and discharging the output capacitors. To achieve small output voltage ripple, choose a low-ESR output capacitor like ceramic capacitor. For ceramic capacitors, the capacitance dominates the output ripple. For simplification, the output voltage ripple can be estimated by Equation 7 desired.

(7)

Where

- is the output voltage ripple
- $f_{sw}$  is the switching frequency
- L is the inductance of inductor
- $C_{OUT}$  is the output capacitance
- $V_{OUT}$  is the output voltage
- $V_{IN}$  is the input voltage

Due to capacitor's degrading under DC bias, the bias voltage can significantly reduce capacitance. Ceramic capacitors can lose most of their red a ami
